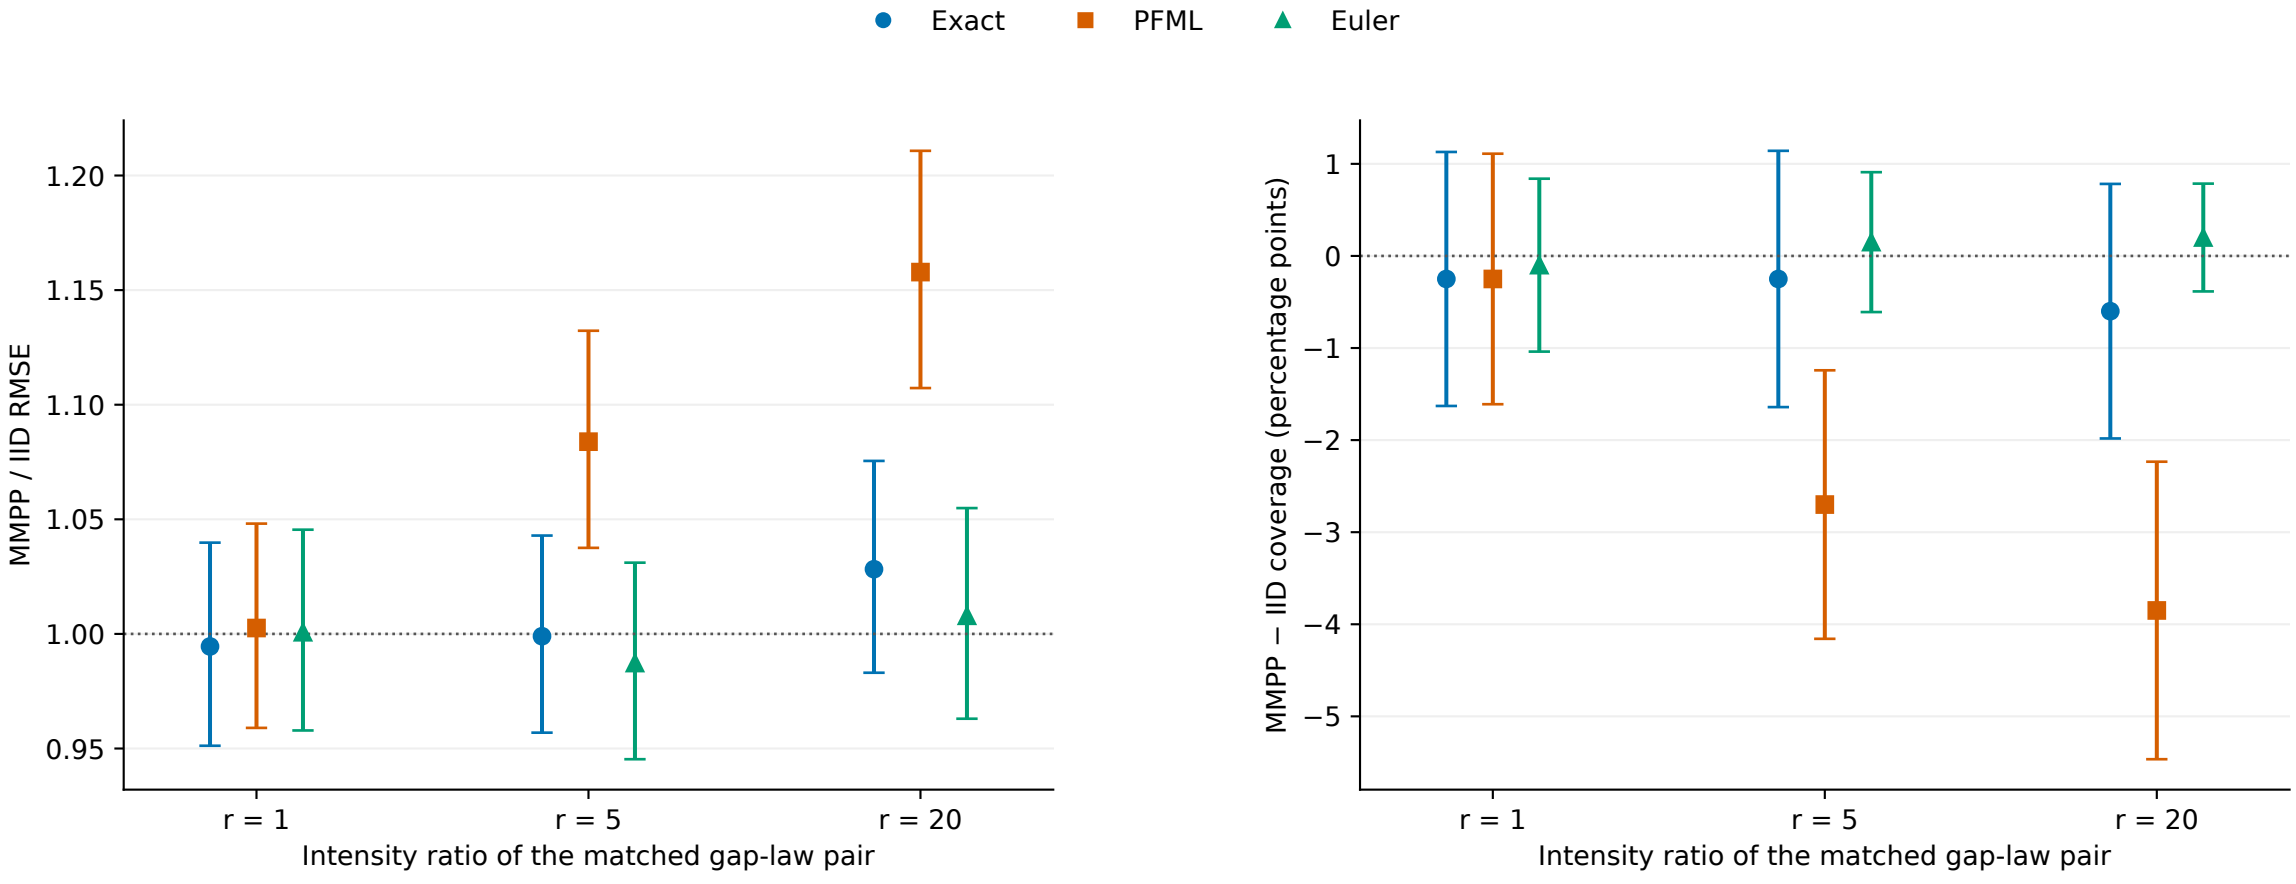
F8 Mean estimation under clustered observation times

Exploratory E4 | n = 1,000 | q = 0.5 | R = 2,000 independent paths per cell



Bars: pointwise 95% Monte Carlo intervals, using independent-cell formulas; positive RMSE-ratio limits use the log-delta method.
MMPP and IID share the entire one-gap marginal and declared floor rule. Their contrast includes realized-span consequences.
PFML μ shows increased RMSE and reduced coverage at r=5 and r=20; the comparison does not establish a mean-bias shift.
PFML/Euler Wald covariance remains model-based. All parameters and matched contrasts are retained in the supplement.
