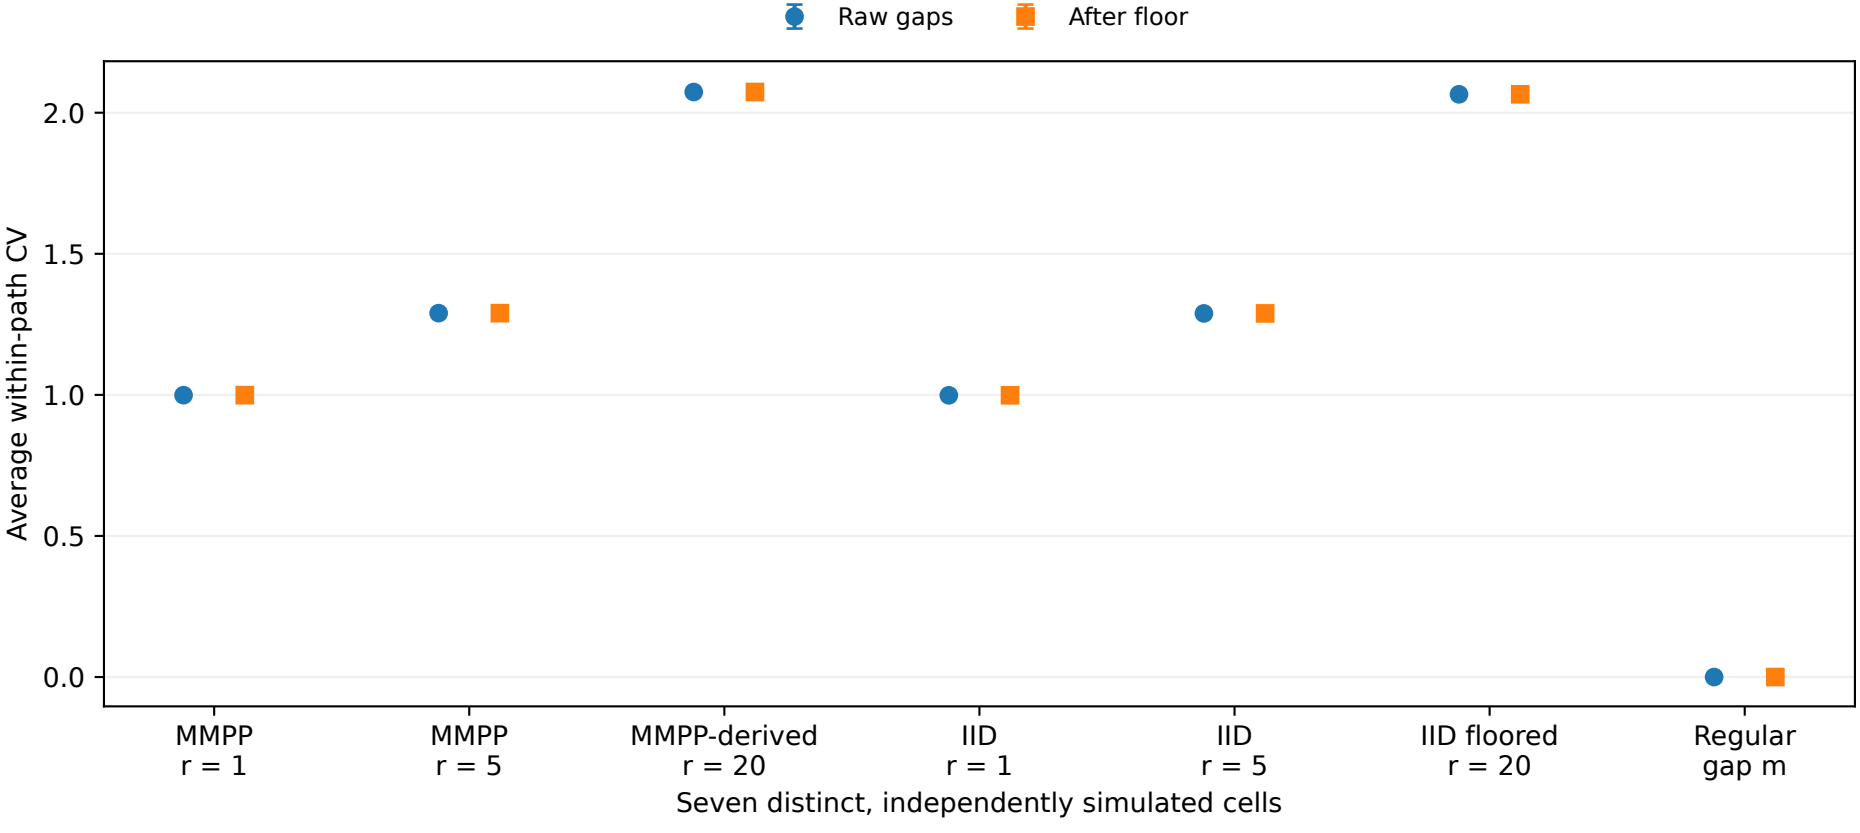
Average within-path gap CV

E4 exploratory experiment | R = 2,000 per cell | n = 1,000 | θm = 0.5



Average within-path CV is not the CV of the pooled marginal gap law; finite-path variability and dependence can affect it. Bars are 1.96 Monte Carlo standard errors across independent source paths, never across dependent gaps or repeated estimators. Only r = 20 is floored; no renormalization or hidden-chain evolution through floor padding occurs. Near-overlap of raw and floored points is retained.
